

Reading Passage 1

You should spend about 20 minutes on **Questions 1-13**, which are based on Reading Passage 1 below.

Communicating In Colour

There are more than 160 known species of chameleons. The main distribution is in Africa and Madagascar, and other tropical regions, although some species are also found in parts of southern Europe and Asia. There are introduced populations in Hawaii and probably in California and Florida too.

New species are still discovered quite frequently. Dr. Andrew Marshall, a conservationist from York University, was surveying monkeys in Tanzania. Accidentally, he stumbled across a twig snake in the Magombera forest, which, frightened, coughed up a chameleon and fled. Though a colleague persuaded him not to touch it because of the venom's risk, Marshall suspected it might be a new species and took a photograph to send to colleagues, who confirmed his suspicions. *Kinyongia Magombera*, literally "the chameleon from Magombera," is the result, and the fact it was not easy to identify is precisely what made it unique. The most remarkable features of chameleons are their ability to change colour and ability rivalled only by cuttlefish and octopi in the animal kingdom. Because of this, colour is not the best thing for telling chameleons apart, and different species are usually identified based on the patterning and shape of the head, and the arrangement of scales. In this case, it was the bulge of scales on the chameleon's nose.

Chameleons can use colour for both communication and camouflage by switching from bright, showy colours to the exact colour of a twig within seconds. They show an extraordinary range of colours, from nearly black to bright blues, oranges, pinks, and greens, even several at once. A popular misconception is that chameleons can match whatever background they are placed on, whether a chequered red and yellow shirt or a Smartie box. But each species has a characteristic set of cells containing pigment distributed over their bodies in a specific pattern, which determines the range of colours and patterns they can show. To the great disappointment of many children, placing a chameleon on a Smartie box generally results in a stressed, confused, dark grey or mottled chameleon.

Chameleons are visual animals with excellent eyesight, and they communicate with colour. When two male dwarf chameleons encounter each other, each shows its brightest colours. They puff out their throats and present themselves side-on with their bodies flattened to appear as large as possible and show off their colours. This enables them to assess each other from a distance. If one is clearly superior, the other quickly changes to submissive

colouration, usually a dull combination of greys or browns. If the opponents are closely matched and both maintain their bright colours, the contest can escalate to physical fighting and jaw-locking, each trying to push each other along the branch in a contest of strength. Eventually, the loser will signal his defeat with submissive colouration.

Females also have aggressive displays used to repel male attempts at courtship. When courting a female, males display the same bright colours that they use during contests. Most of the time, females are unreceptive and aggressively reject males by displaying a contrasting light and dark colour pattern, with their mouths open and moving their bodies rapidly from side to side. If the male continues to court a female, she often chases and bites him until he retreats. The range of colour-change during female displays, although impressive, is not as great as that shown by males.

Many people assume that colour change evolved to enable chameleons to match a greater variety of backgrounds in their environment. If this was the case, then chameleons' ability to change colours should be associated with the range of background colours in the chameleon's habitat, but there is no evidence for such a pattern. For example, forest habitats might have a greater range of brown and green background colours than grasslands, so forest-dwelling species might be expected to have higher colour change powers. Instead, the males whose display colours are the most eye-catching, show the greatest colour change. Their displays are composed of colours that contrast highly with each other and the background vegetation. This suggests that the species that evolved the most impressive capacities for colour change did so to enable them to intimidate rivals or attract mates rather than to facilitate camouflage.

How do we know that chameleon display colours are eye-catching to another chameleon – or, for that matter, to a predatory bird? Getting a view from the perspective of chameleons or their bird predators requires information on the chameleon's or bird's visual system and how their brains might process visual information. This is because the perceived colours of an object depend on the brain's wiring as on the physical properties of the object itself. Luckily, recent scientific advances have made it possible to obtain such measurements in the field, and information on visual systems of a variety of animals is becoming increasingly available.

The spectacular diversity of colours and ornaments in nature has inspired biologists for centuries. But if we want to understand the function and evolution of animal colour patterns, we need to know how they are perceived by the animals themselves – or their predators. After all, camouflage and conspicuousness are in the eye of the beholder.

Questions 1-4

Answer the questions below.

Choose **NO MORE THAN THREE WORDS** from the passage for each answer.

Write your answers in boxes 1-4 on your answer sheet.

- 1 What kind of climate do most chameleons live in?
- 2 Which animal caught a chameleon from an undiscovered species?
- 3 What was the new species named after?
- 4 Which part of the body is unique to the species Kinyongia Magombera?

Questions 5-13

Do the following statements agree with the information given in Reading Passage 1? In boxes 5-13 on your answer sheet, write

TRUE if the statement agrees with the information

FALSE if the statement contradicts the information

NOT GIVEN if there is no information on this

- 5 Few creatures can change colour as effectively as cuttlefish.
- 6 Chameleons can imitate a pattern provided there are only two colours.
- 7 Chameleons appear to enjoy trying out new colours.
- 8 Size matters more than colour when male chameleons compete.
- 9 After a fight, the defeated male hides among branches of a tree.
- 10 Females use colour and movement to discourage males.
- 11 The popular explanation of why chameleons change colour has been proved wrong.
- 12 There are more predators of chameleons in grassland habitats than in others.
- 13 Measuring animals' visual systems necessitates removing them from their habitat.
